September 26, 2024

Identifying the Problem

In translational research, exploring data is a major challenge because:

- There is a need to analyze large amounts of data from different fields, like genomic data, clinical trial results, or medical images.
- This data often uses very technical language, which makes it hard to understand and apply the findings quickly in real healthcare situations.

Exploring the solution

Large Language Models (LLMs) can help address the challenges of **data exploration** in translational research in several ways:

- Translate complex scientific language into simpler terms.
- Conduct efficient literature review
- Identify potential applications and treatment options
- Integrate multidisciplinary knowledge
- Generating new hypotheses and recommendations

Barriers to Implementation

- Mitigate hallucinations and inaccuracies
- Address limited domain expertise
- Ensure interpretability and transparency
- Manage computational cost and scalability
- Handling ethical and privacy concerns

Data architecture to explore data in translational research
